Lecture 3: Exceptional Control Flow

CS 3281

Daniel Balasubramanian, Shervin Hajiamini

Lecture slides borrowed and adapted from the CMU course: Computer Systems: A Programmer's Perspective

Today

- **Exceptional Control Flow**
- Exceptions
- Processes
- Process Control

Control Flow

- Processors do only one thing:
  - From startup to shutdown, a CPU reads and executes (interprets) a sequence of instructions, one at a time
  - This sequence is the CPU's *control flow* (or *flow of control*)

Physical control flow

Time

<startup>
inst_1
inst_2
inst_3
…
inst_n
<shutdown>

Altering the Control Flow

- You know two mechanisms for changing control flow:
  - Jumps and branches
  - Call and return
    - *These react to changes in program state*
- Insufficient for a useful system: difficult to react to changes in system state
  - Examples of changes in system state:
    - Data arrives from a disk or a network adapter
    - Instruction divides by zero
    - User hits Ctrl-C at the keyboard
    - System timer expires
- System needs mechanisms for “exceptional control flow”

Exceptional Control Flow

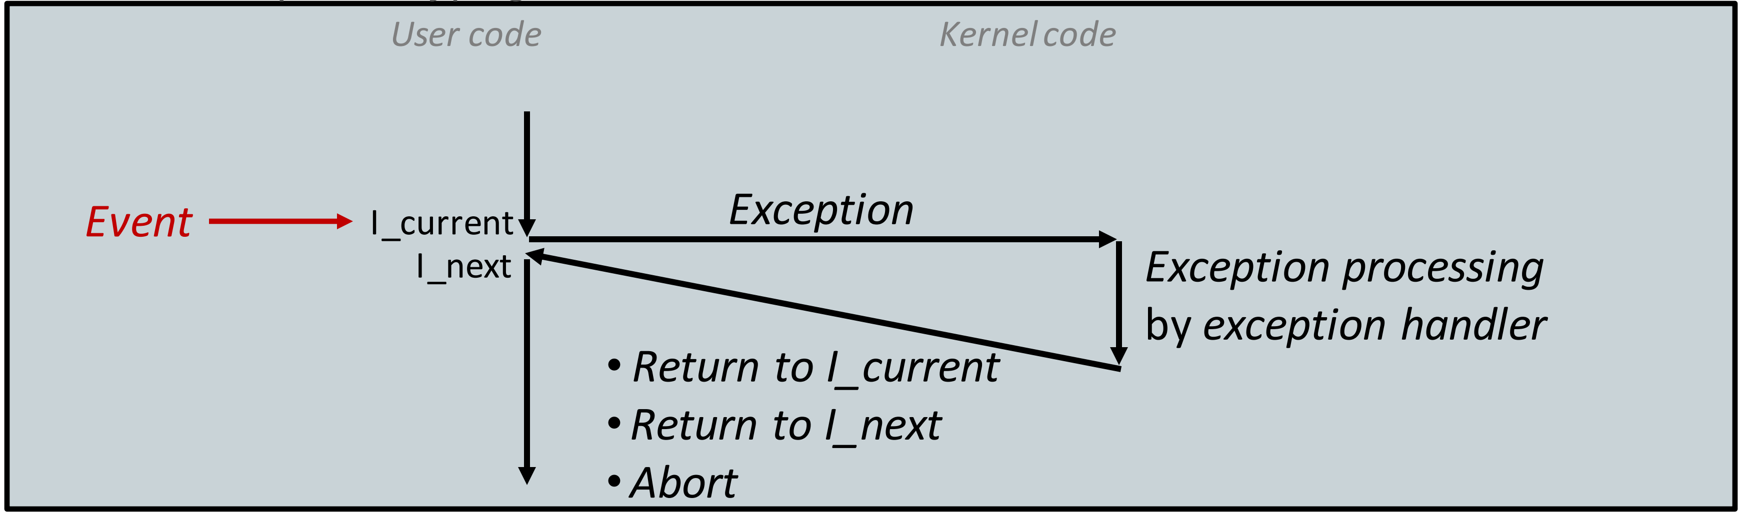
- Exists at all levels of a computer system
- Low-level mechanisms
  - 1. Exceptions
    - Change in control flow in response to a system event (i.e., change in system state)
    - Implemented using combination of hardware and OS software
- High-level mechanisms
  - 1. Process context switch
    - Implemented by OS software and hardware timer
  - 2. Signals
    - Implemented by OS software
  - 3. Nonlocal jumps: setjmp() and longjmp()
    - Implemented by C runtime library

Today

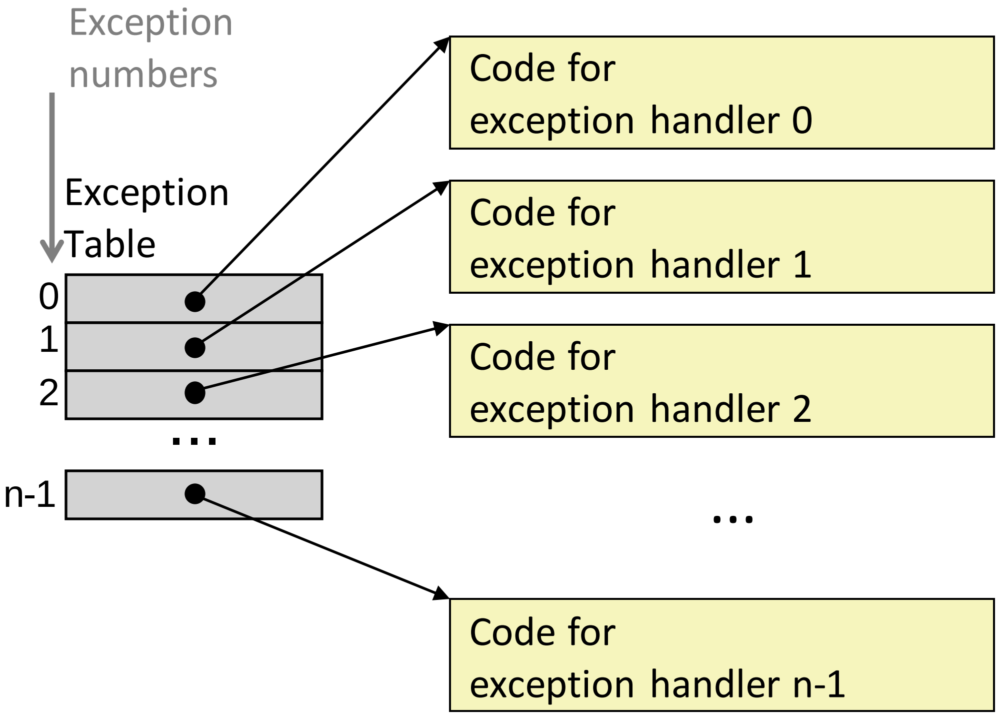
- Exceptional Control Flow
- **Exceptions**
- Processes
- Process Control

Exceptions

- An exception is a transfer of control to the OS kernel in response to some event (i.e., change in processor state)
  - Kernel is the memory-resident part of the OS
  - Examples of events: Divide by 0, arithmetic overflow, page fault, I/O request completes, typing Ctrl-C



Exception tables



- Each type of event has a unique exception number k
- k = index into exception table (a.k.a. interrupt vector)
- Handler k is called each time exception k occurs

Asynchronous Exceptions (Interrupts)

- Caused by events external to the processor
  - Indicated by setting the processor's interrupt pin
  - Handler returns to "next" instruction

- Examples:
  - Timer interrupt
    - Every few ms, an external timer chip triggers an interrupt
    - Used by the kernel to take back control from user programs
  - I/O interrupt from external device
    - Hitting Ctrl-C at the keyboard
    - Arrival of a packet from a network
    - Arrival of data from a disk

Synchronous Exceptions

- Caused by events that occur as a result of executing an instruction:
    - Traps
        - Intentional
        - Examples: system calls, breakpoint traps, special instructions
        - Returns control to “next” instruction
    - Faults
        - Unintentional but possibly recoverable
        - Examples: page faults (recoverable), protection faults (unrecoverable), floating point exceptions
        - Either re-executes faulting (“current”) instruction or aborts
    - Aborts
        - Unintentional and unrecoverable
        - Examples: illegal instruction, parity error, machine check
        - Aborts current program

System Calls

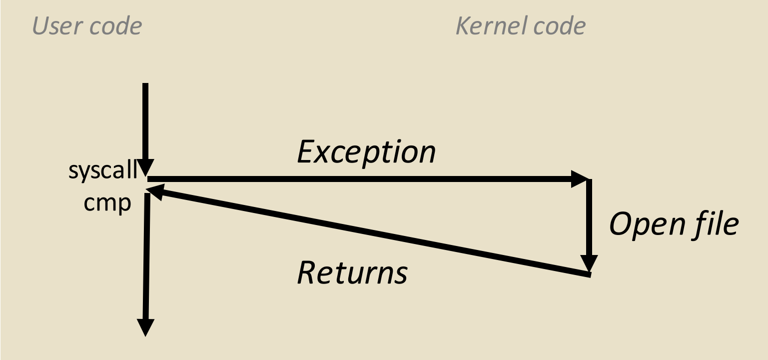
- Each x86-64 system call has a unique ID number
- Examples:

Number	***Name***	***Description***
0	`read`	Read file
1	`write`	Write file
2	`open`	Open file
3	`close`	Close file
4	`stat`	Get info about file
57	`fork`	Create process
59	`execve`	Execute a program
60	`_exit`	Terminate process
62	`kill`	Send signal to process

System Call Example: Opening File

- User calls: `open(filename, options)`
- Calls `__open` function, which invokes system call instruction `syscall`

```
00000000000e5d70 <__open>:
...
e5d79:   b8 02 00 00 00      mov  $0x2,%eax  # open is syscall #2
e5d7e:   0f 05               syscall         # Return value in %rax
e5d80:   48 3d 01 f0 ff ff   cmp  $0xfffffffffffff001,%rax
...
e5dfa:   c3                  retq
```



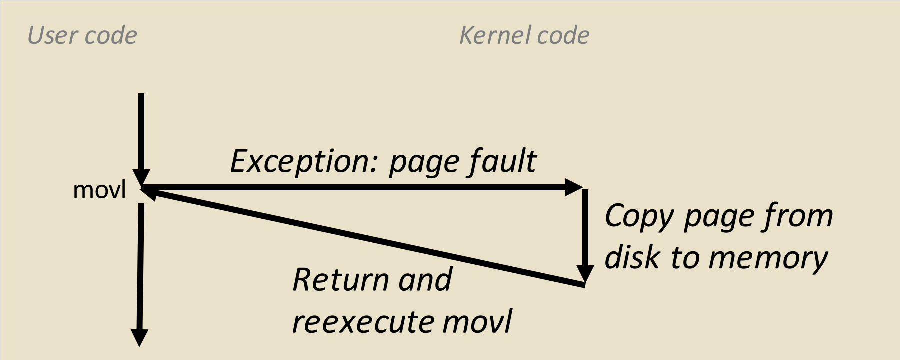
- `%eax` contains syscall number
- Other arguments in `%rdi`, `%rsi`, `%rdx`, `%r10`, `%r8`, `%r9`
- Return value in `%rax`
- Negative value is an error corresponding to negative `errno`

Fault Example: Page Fault

- User writes to memory location
- That portion (page) of user's memory is currently on disk

```
int a[1000];
main ()
{
    a[500] = 13;
}
```

```
80483b7: c7 05 10 9d 04 08 0d          movl   $0xd,0x8049d10
```

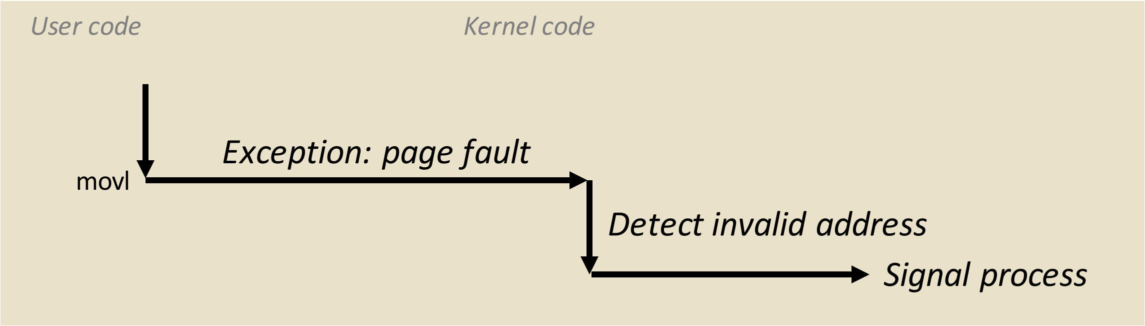


Fault Example: Invalid Memory Reference

- Sends `SIGSEGV` signal to user process
- User process exits with “segmentation fault”

```
int a[1000];
main ()
{
    a[5000] = 13;
}
```

```
80483b7: c7 05 60 e3 04 08 0d          movl   $0xd,0x804e360
```

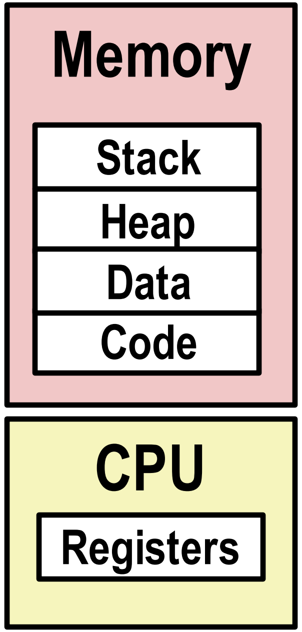


Today

- Exceptional Control Flow
- Exceptions
- **Processes**
- Process Control

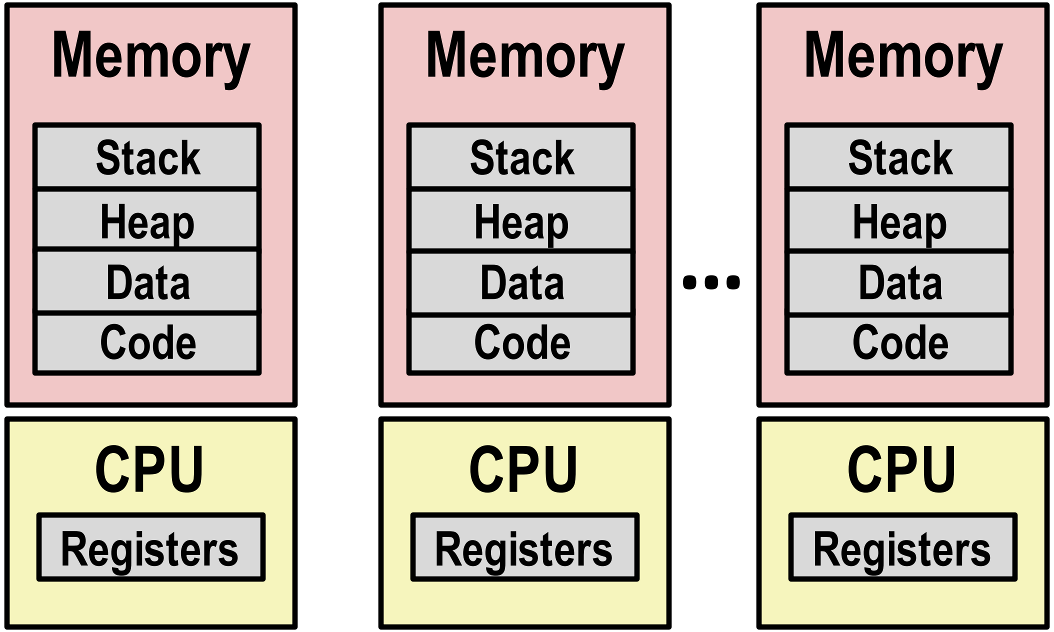
Processes

- Definition: A process is an instance of a running program.
  - One of the most profound ideas in computer science
  - Not the same as "program" or "processor"
- Process provides each program with two key abstractions:
  - Logical control flow
    - Each program seems to have exclusive use of the CPU
    - Provided by kernel mechanism called context switching
  - Private address space
    - Each program seems to have exclusive use of main memory.
    - Provided by kernel mechanism called virtual memory



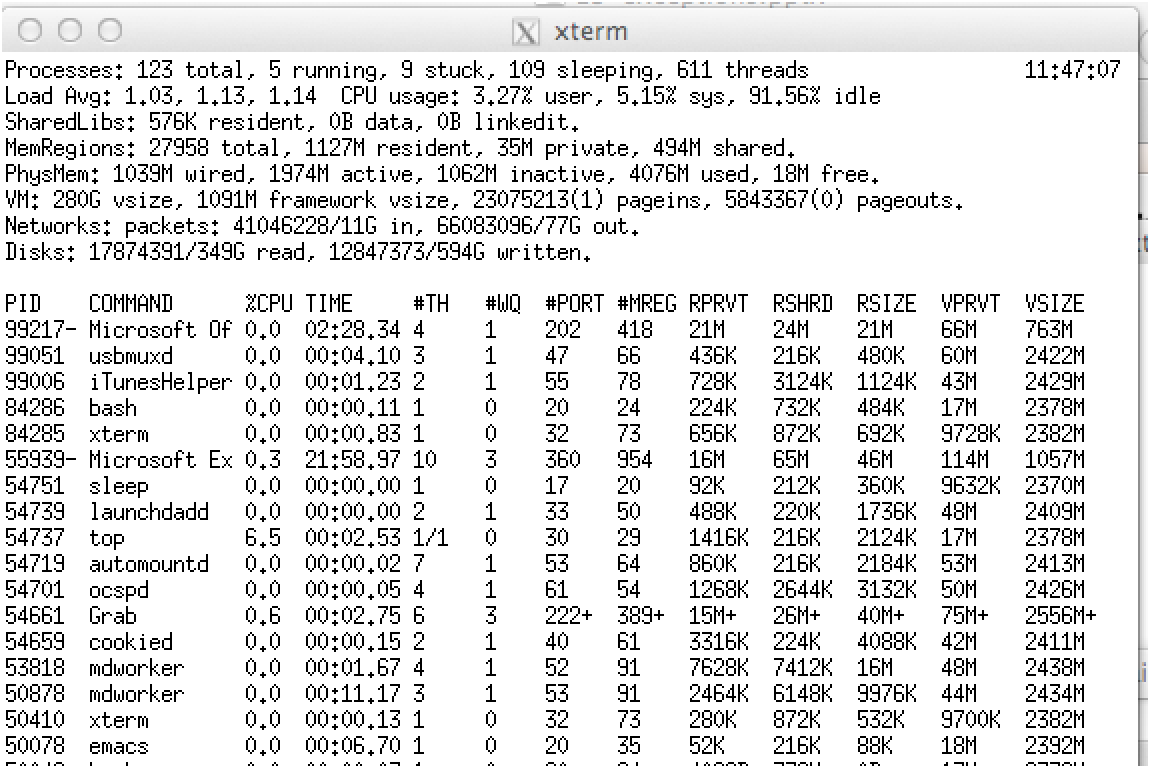
Multiprocessing: The Illusion

- Computer runs many processes simultaneously
  - Applications for one or more users
    - Web browsers, email clients, editors, …
  - Background tasks
    - Monitoring network & I/O devices



Multiprocessing Example

- Running program “top” on Mac
  - System has 123 processes, 5 of which are active
  - Identified by Process ID (PID)



```
xterm
Processes: 123 total, 5 running, 9 stuck, 109 sleeping, 611 threads               11:47:07
Load Avg: 1.03, 1.13, 1.14  CPU usage: 3.27% user, 5.15% sys, 91.56% idle
SharedLibs: 576K resident, 0B data, 0B linkedit.
MemRegions: 27958 total, 1127M resident, 35M private, 494M shared.
PhysMem: 1039M wired, 1974M active, 1062M inactive, 4076M used, 18M free.
VM: 280G vsize, 1091M framework vsize, 23075213(1) pageins, 5843367(0) pageouts.
Networks: packets: 41046228/11G in, 66083096/77G out.
Disks: 17874391/349G read, 12847373/594G written.

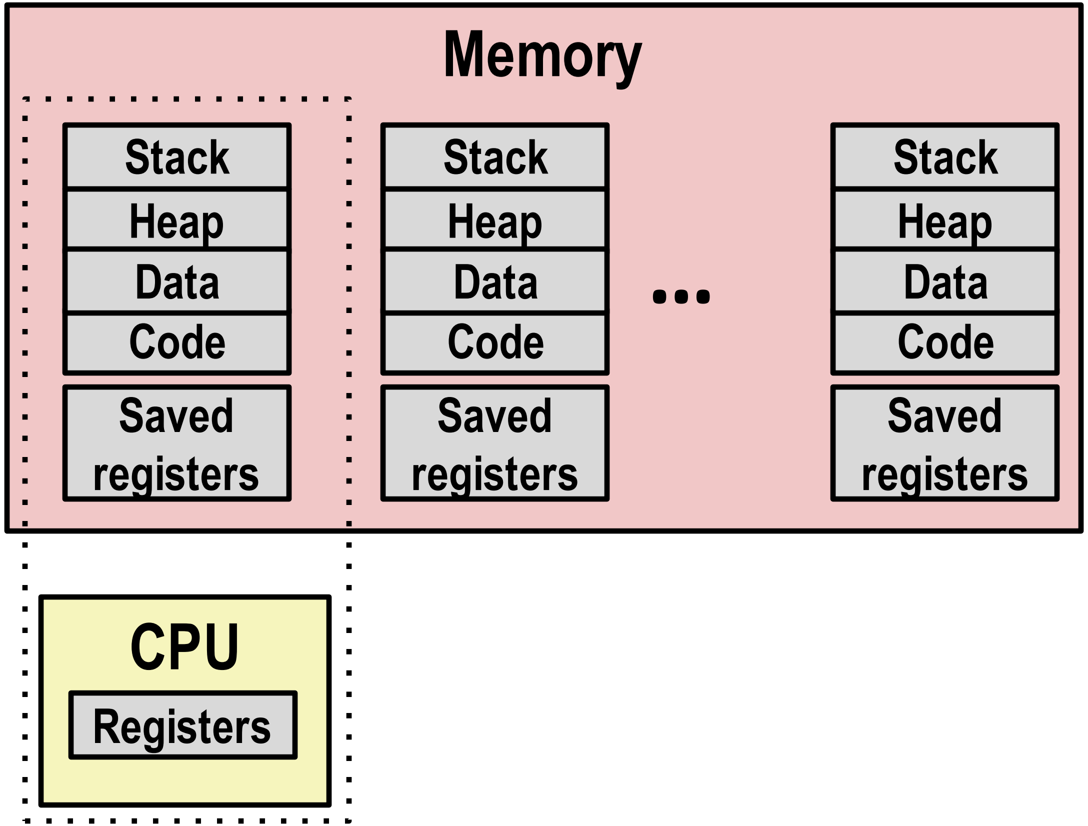
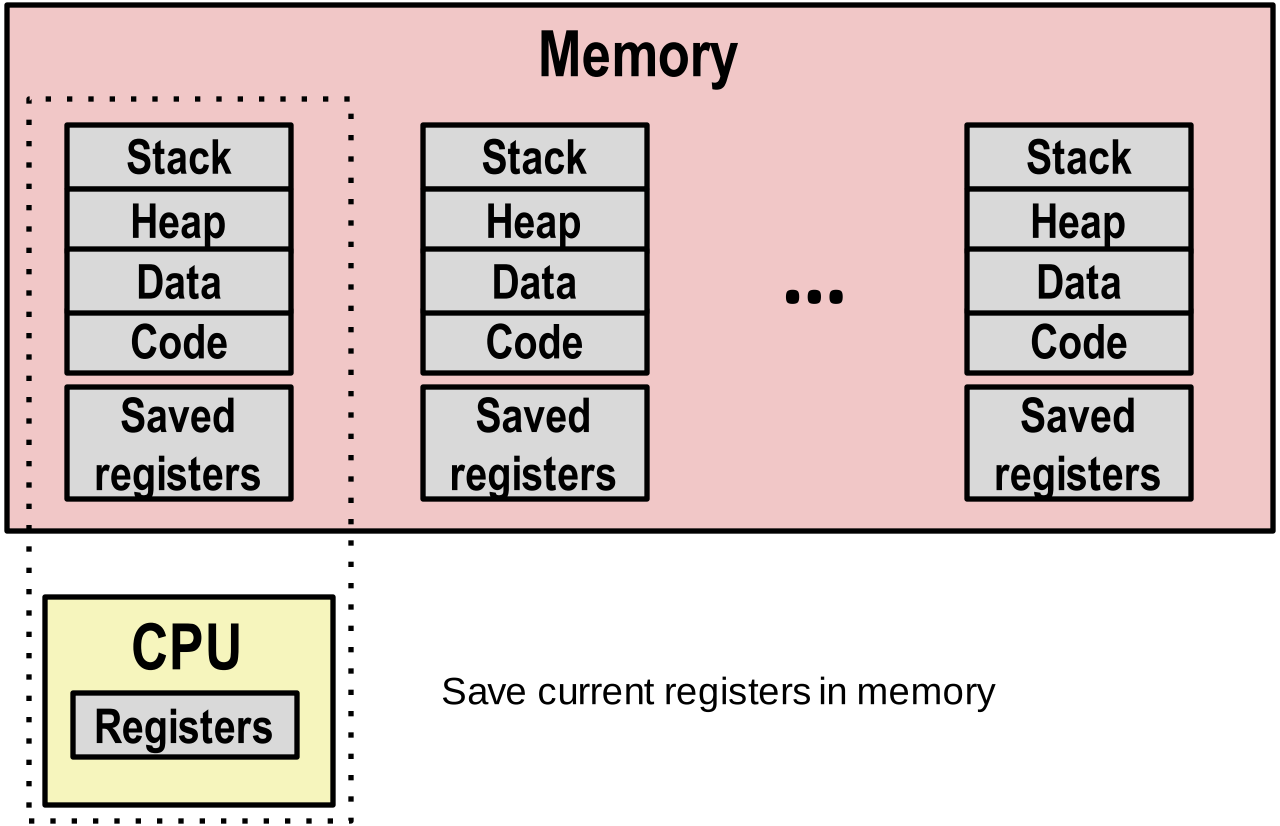
```

Multiprocessing: The (Traditional) Reality

- Single processor executes multiple processes concurrently
  - Process executions interleaved (multitasking)
  - Address spaces managed by virtual memory system (later in course)
  - Register values for nonexecuting processes saved in memory

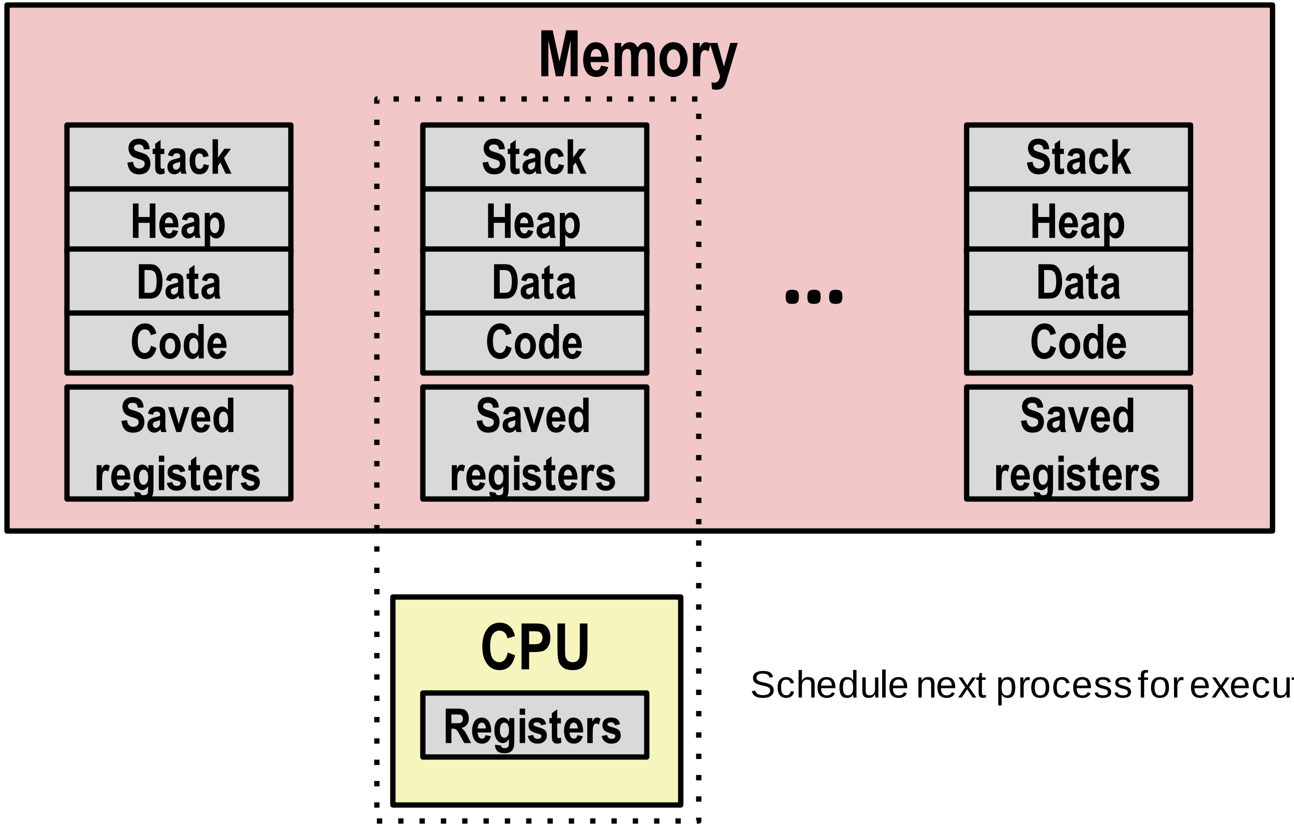


Multiprocessing: The (Traditional) Reality



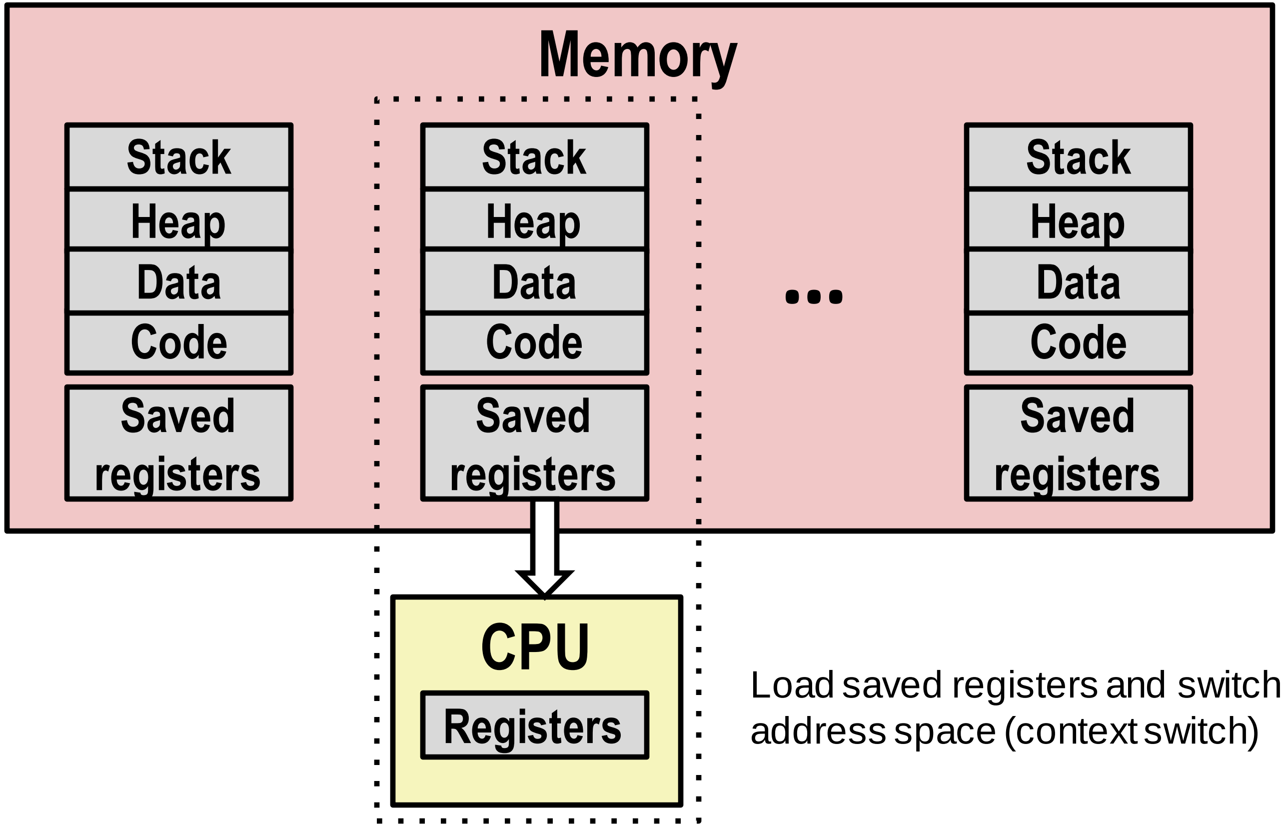
Save current registers in memory

Multiprocessing: The (Traditional) Reality



Schedule next process for execution

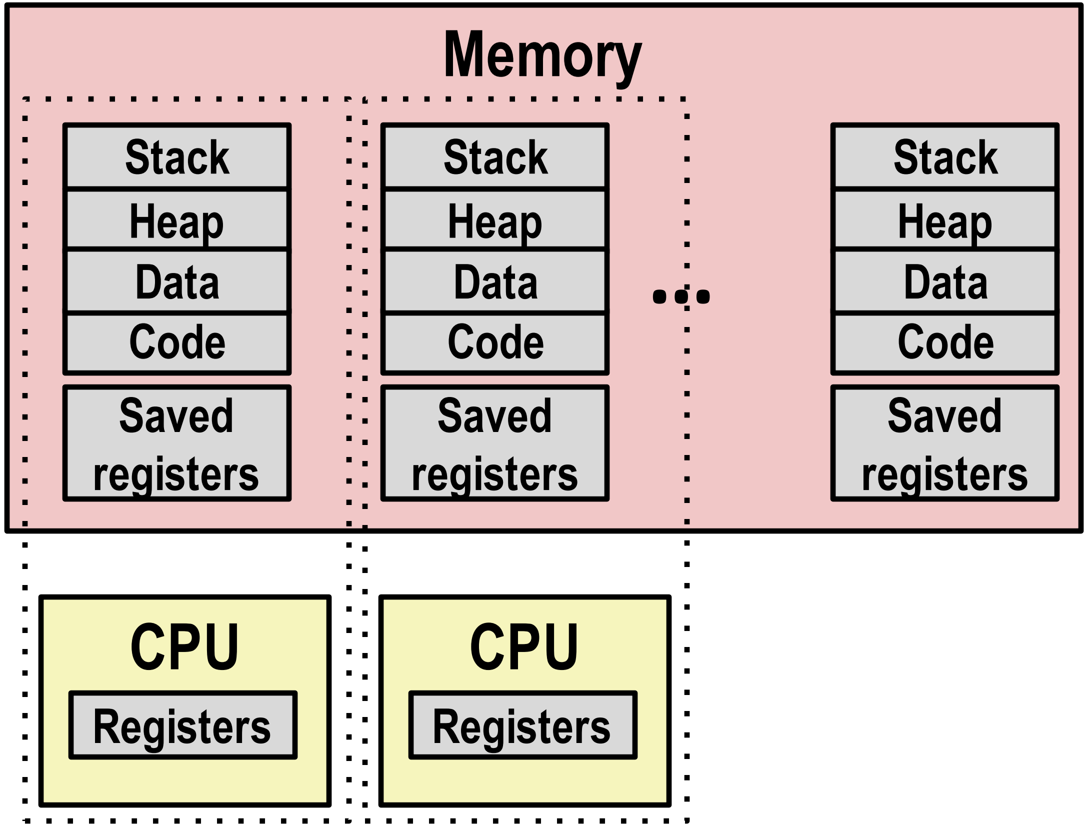
Multiprocessing: The (Traditional) Reality



Load saved registers and switch address space (context switch)

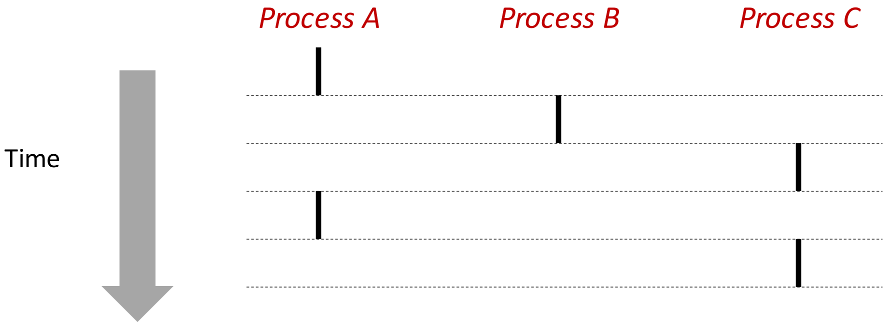
Multiprocessing: The (Modern) Reality

- Multicore processors
  - Multiple CPUs on single chip
  - Share main memory (and some of the caches)
  - Each can execute a separate process
  - Scheduling of processors onto cores done by kernel



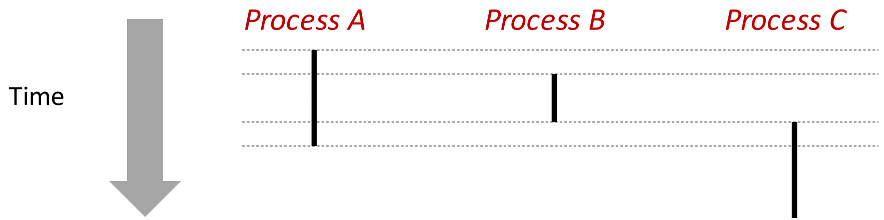
Concurrent Processes

- Each process is a logical control flow.
- Two processes *run* *concurrently* (*are concurrent)* if their flows overlap in time
- Otherwise, they are *sequential*
- Examples (running on single core):
  - Concurrent: A & B, A & C
  - Sequential: B & C



User View of Concurrent Processes

- Control flows for concurrent processes are physically disjoint in time
- However, we can think of concurrent processes as running in parallel with each other



Context Switching

- Processes are managed by a shared chunk of memory-resident OS code called the *kernel*
    - Important: the kernel is not a separate process, but rather runs as part of some existing process.
- Control flow passes from one process to another via a *context switch*
